Who is in favor of enlargement?

Determinants of support for EU membership in the candidate countries' referenda

Abstract

This paper investigates both macro and micro determinants of EU support in the new member and candidate countries of the EU. It is found that favorable individual and regional characteristics are positively correlated with support for accession and voter participation. In contrast, those who should benefit from future EU transfers are less likely to participate and/or support EU membership. It is therefore argued that voters in the new member states assign greater weight on future benefits from liberalization and integration than on potential gains through redistribution. This pattern is similar to the support for market-oriented reforms, suggesting that voters may see EU membership as the ultimate step in the transition from communism to democracy and market economy.

1. Introduction

It seems indisputable that the enlargement of the European Union, which occurred on May 1st 2004, will be vastly beneficial for the ten new member states from Central and Eastern Europe and the Mediterranean.[1] Yet, when nine prospective entrants held referenda on accession during the course of Spring and Summer 2003,[2] it transpired that EU membership was not always an easy sell. While all of the referenda eventually resulted in the approval of accession, this positive outcome came on the background of low participation rates. In Poland and Slovakia, for example, participation barely exceeded the legally mandated threshold of 50% required to make the outcome valid.[3] It is also interesting to note that only in two countries (Lithuania and Slovenia) did EU membership enjoy the support of more than half of all eligible voters.[4] Indeed, opinion poll results suggest that the most enthusiastic Europeans are the citizens of those countries that, to date, have not been offered EU membership: Bulgaria, Romania and Turkey.

These observations show that despite the positive final outcome of the referenda, support for EU membership is not universally shared within the new member countries. The consequences of accession are likely to diverge across various socio-economic groups, with some gaining and others losing. Therefore, assuming voters are prospectively oriented and thus take their future well being into account when casting their vote, the extent of support for EU membership should reflect the distribution of expected gains and losses.[5] In order to gain insights into the factors that shape support for EU membership, this paper analyses voting behavior in the accession referenda utilizing two previously untapped data sources. First, the actual referenda results at the regional level in seven candidate countries are considered: Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland and Slovakia. Second,

---

[1] Cyprus, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Slovakia and Slovenia joined the EU on 1st May 2004. Bulgaria and Romania are tentatively scheduled to become members as of 2007, while no accession date has been set for Turkey.

[2] Cyprus approved the accession in the legislature, thus being the only candidate country that did not hold a referendum.

[3] No such threshold was in effect in the Czech Republic, whereas Hungary required either at least 50% participation or an affirmative vote by at least 25% of eligible voters.

[4] In the presence of minimum turnout requirements, non-participation can indicate either indifference or strategic considerations, whereby one abstains in the hope of driving the participation rate below the legally mandated threshold.

[5] An alternative explanation for the low turnout rates is that voters used the accession referendum to express their discontent with the current government. However, if membership in the EU is going to be vastly beneficial for most voters in the new member and candidate countries, forgoing these gains seems a high price for sending a message to the incumbent government.

this analysis is complemented with individual data on voting intentions in the EU referendum from the March/April 2002 Candidate Countries Eurobarometer (CCEB) survey covering all 13 candidate countries.

Accession will affect the citizens of the new member countries in numerous ways.[6] As previous studies (e.g., Gabel, 1998, 2000) have shown that utilitarian considerations are one of the most important determinants of support for the EU, this paper focuses on the economic implications of membership, thus omitting political and emotional considerations, such as the dilution or loss of national identity, etc. We investigate two broad categories of effects. First, the new members can take full advantage of economic integration within the European Single Market, bringing with it the free movement of goods, capital and – albeit with a lag of up to seven years – labor. While this opens up important opportunities for the new entrants, it also brings considerable challenges (e.g., increased competitive pressure and more stringent EU regulations). Second, as the new members are relatively poor compared to the EU-15 states, stricken with high unemployment and, in some cases, large agricultural sectors, they should benefit from redistribution within the EU channeled through the Structural and Cohesion funds and the Common Agricultural Policy (CAP).

As the candidate countries display considerable economic disparities both at the individual and regional level, the variation in expected net gains from accession among individuals and regions should be considerable. An individual's expected net gain from EU membership, should to a large extent, depend on his individual characteristics such as age, education, employment or current income. In addition, as regions differ in their underlying economic structure, the regional repercussions of accession will also be uneven – a region predominantly oriented towards agriculture or heavy industry, for instance, will fare differently from one dominated by service industries. As a large part of EU spending is explicitly linked to regional characteristics such as average per-capita income or unemployment, individual regions' entitlement to transfers from the EU will differ substantially. This paper explicitly controls for these kinds of effects in order to assess their impact on support for EU membership.

---

[6] A number of recent studies have assessed the expected benefits of EU membership using sophisticated modelling techniques (see for example Baldwin, Francois and Portes, 1997; Breuss, 2001; and Lejour, de Mooij and Nahuis, 2001; and DIW, 2002).

As previous research has shown (e.g., Doyle and Fidrmuc, 2003), the outcome of the economic reform process affected different socio-economic groups and regions in diverging ways, with some groups gaining and other losing. Such studies find that the "winners" of the transition process are generally young well-educated individuals, who can take advantage of the new opportunities available in the market economy. The "losers", conversely, are whose possessing human capital characteristics that may be outdated in a market economy and find it difficult to adjust to the new environment e.g., elderly blue-collar workers with little education. Typically, the winners of the transition process tend to support the continuation of reforms, while the losers oppose them. This paper therefore extends this analysis by examining support for the pinnacle of the transition process - membership to the European Union. It is likely, therefore, that support for EU membership may follow a similar pattern.

This paper differs from related literature in two ways. First, while support for the EU has attracted considerable attention in the academic literature, most previous studies have been limited to considering the current EU members (see Gabel and Palmer, 1995; Gabel and Whitten, 1997, and the references therein). Second, those few studies that do analyze support for EU membership in the candidate countries typically rely on individual survey data which was collected in the early to mid 1990s: the Central and Eastern Eurobarometer, commissioned by the European Commission and discontinued in 1998 (see Tucker, Pacek and Berinsky, 2002; Tverdova and Anderson, 2003; and Kemmerling, 2003). These analyses are based on respondents' statements about their intended voting in a referendum on EU membership and their support for the EU. However, given the time lag between these surveys and the actual referenda, which only took place in 2003, the respondents opinions might have been different had the prospect of membership been more tangible.

This analysis, in contrast, uses both the actual (regional) results of the referenda, and individual survey data from the recently reinstated Candidate Countries' Eurobarometer, collected in Spring 2002, approximately one year before the actual referenda took place. One study similar to this, by Markowski and Tucker (2003), similarly use opinion-poll data (from a different source) and the actual regional results in their analysis of Poland.

Finally, much of the previous literature, whether on current members or the candidate countries, relies on various attitudinal variables (in addition to socio-economic characteristics) such as the respondents' ideological identification, political

opinions, or their attitude towards the EU to explain support for integration. These studies find that respondents who expect their country to benefit from accession to the EU intend to vote in favor of membership. One potential problem with using such attitudinal variables to explain vote choice is that it is difficult to disentangle the endogeneity between the two. Moreover, previous studies (Wleizen, Franklin and Twiggs, 1996; and Doyle, 2004) find that attitudinal variables are often influenced by vote choice and one's socio-economic characteristics.

Therefore, to avoid such endogeneity problems, this analysis refrains from using attitudinal variables and instead concentrates exclusively on the respondents' socio-economic characteristics. As political opinions and attitudes reflect one's age, education, economic well-being and social class, focusing on such characteristics tells us more about the primary determinants of voting behavior. Moreover, identifying the trigger factors that underlie support for EU membership is important if one seeks to understand how changes in objective economic conditions impact support for EU membership (for instance, a permanent change in a respondent's employment status or income may translate into simultaneous changes in her political attitudes and support for the EU).

The following section briefly reviews the history of this recent enlargement. Section 3 discusses the likely gains and losses associated with accession to the EU. Section 4 introduces the data used in the analysis and sections 5 and 6 present the empirical findings. Finally, the last section discusses the results and derives some conclusions.

2. History of the 5th enlargement

On May 1st 2004 the EU experienced its fifth and most ambitious enlargement to date, as it incorporated eight Central and East European (Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Slovakia and Slovenia) and two Mediterranean countries (Malta and Cyprus), with Bulgaria and Romania set to join in 2007. This enlargement symbolically began in 1989 after the break-up of the Soviet block, when the EU declared that it would welcome the countries of Central and Eastern Europe to join the Union. However, it was not until the Copenhagen European Council in 1993 that this invitation was officially issued, on the condition that the countries could join once they satisfied the political and economic conditions necessary for membership

and implemented the *acquis communautaire* (i.e., the body of EU norms and regulations). In the meantime, the EU gradually removed long-standing import quotas, extended the Generalized System of Preferences, concluded Trade and Co-operation Agreements with several of the post-communist countries and created the PHARE Program which provided financial aid to help the transition to a market economy (EUROPA, 2003). Throughout the 1990's the Association Agreements, also known as the Europe Agreements, established the legal basis for bilateral relations between the EU and the potential candidate countries. A significant outcome of these Agreements was the creation a free trade area for most industrial goods between the EU and the candidate countries.

It was not until March 1998 that the accession negotiations actually began with six of the applicant countries (Czech Republic, Estonia, Hungary, Poland, Slovenia and Cyprus), otherwise known as the first-wave applicants. In October 1999, the negotiations were extended to include Slovakia, Latvia, Lithuania, Romania, Bulgaria and Malta. By December 2002 accession negotiations were closed and in April 2003 Treaties of Accession were signed with the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Slovak Republic, Slovenia, Malta and Cyprus. Nine of these countries held referenda in the course of 2003 to formally ask their citizens if they wish to become members of the Union, while Cyprus put the decision to the legislature. All of the referenda delivered an affirmative decision. Once the current EU members ratified the Accession Treaties, all ten acceding countries became full members of the EU in May 2004, in time to participate in the June 2004 European Parliamentary elections and in the next Inter-Governmental Conference.

3. Benefits and costs of EU membership

EU membership can be thought of as affecting the economic wellbeing of citizens of the new member countries through at least two distinct channels: economic integration and redistribution. These two channels are likely to have different implications for various socio-economic groups. By observing how specific individual and regional characteristics correlate with voting behavior, one can make inferences about the expected impact of enlargement on individuals or regions possessing those characteristics.

3.1 Benefits from economic integration

Accession to the EU allows the member countries to participate in the European Single Economic Market with its free and unhindered movement of commodities, capital and labor[7]. This opens up new opportunities in the areas of trade, investment and employment for firms and individuals from the new members.[8] How this affects individual voters, however, depends on a number of considerations, most notably mobility of factors of production across sectors, and the degree of protectionism.

When factors of production are mobile across sectors, the Heckscher-Ohlin model of trade suggests that integration benefits the abundant factors and hurts the scarce ones. The typical paradigm therefore is that economic integration brings gains to the owners of capital and to skilled labor in developed countries, and benefits unskilled labor in less developed countries. This occurs as, with falling trade barriers, each country can specialize in producing goods that require its abundant factors (capital and skilled-labor in developed countries, unskilled labor in less-developed countries), and import those that require factors which are in short supply. Therefore, as argued – and documented empirically – by O'Rourke and Sinnott (2001), O'Rourke (2003) and Mayda and Rodrik (2001), highly skilled voters support economic integration in skill-abundant countries while they oppose it in skill-scarce countries, and vice versa for low-skilled workers.

Applying this argument to the new member and candidate countries, however, is not straightforward for two reasons. First, the set of new member and candidate countries is more homogenous than the group of countries analyzed by Mayda and Rodrik and O'Rourke and Sinnott: with the notable exception of Turkey (as well as Bulgaria and Romania), the new members and candidates are all middle-income industrialized countries.[9] Second, they defy the traditional paradigm of trade integration between developed and less developed countries in that, despite being poorer than the old EU members, their labor is highly skilled and educated (Turkey,

---

[7] The old member counties were allowed to impose transitional period of up to seven years on migration and employment of nationals from the new member countries (with the exception of Malta and Cyprus). Only Ireland and the United Kingdom did not take advantage of this provision.

[8] Detailed analyses of the implications of this enlargement for the current and new members at the aggregate level are presented, *inter alii*, by Baldwin, Francois and Portes (1997); Breuss (2001, 2002); Lejour, de Mooij and Nahuis (2001); Boeri *et al.* (2002); Heijdra, Keuschnig and Kohler (2002); and DIW (2002).

[9] In contrast, Mayda and Rodrik and O'Rourke and Sinnott base their analyses on the same data set including both developed and post-communist countries and one developing country (the Philippines).

again, seems to be the main exception). It is therefore difficult to hypothesize whether accession to the EU will benefit mainly highly or low skilled labor in the new member and candidate countries. The standard rich-poor trade-theory paradigm suggest that low skilled labor should be the main winner, however, in view of the relatively high human capital endowments of the new members and candidates, it is conceivable that the gains will accrue predominantly to highly skilled labor. The main prediction that we can formulate based on trade theory thus states that the EU enlargement will benefit owners of capital in the old member countries and labor in the new member countries, as these are the factors of production that are relatively abundant in the two groups of countries.

The preceding discussion applies to the case when factors of production are inter-sectorally mobile, so that firms and workers can move to sectors offering the highest returns. If factors are immobile (or if skills are not transferable across sectors), on the other hand, different predictions are obtained (see the discussion of the specific-factors model in Mayda and Rodrik, 2001). In particular, accession to the European Single Market also translates into more intense competitive pressure and may thus prove costly for those industries that are not internationally competitive or that currently enjoy relatively high protection against imports. While the Association Agreements facilitated gradual liberalization of trade in most manufactured industries, agricultural products continued to enjoy considerable protection. In addition, with membership, the acceding countries have to adopt the EU's Common External Tariff (CET) on imports from third countries. The potential benefits from removing the remaining barriers to trade and adopting the CET, however, depend on the countries' current import tariff rates. Finally, EU membership subjects the new members to EU norms and regulations in matters such as environmental protection, quality standards and safety norms, which necessitated costly adjustment in some industries, and to EU competition policy, which substantially restricts the ability of national governments to subsidize ailing firms.

A potentially important implication of membership in the EU is that the new entrants must commit to enter the EMU. Formally, this condition is not negotiable (although as the recent Swedish referendum on EMU membership illustrates, there is considerable informal flexibility allowing the member countries to postpone EMU membership more or less indefinitely). In principle, the new members could adopt the

8

euro as early as 2006-07, assuming they meet all of the *Maastricht criteria*[10]. EMU membership has two distinct effects.[11] First, it is expected to further encourage trade between the participating countries, thereby amplifying the implications of trade integration discussed above. Second, member countries of the Eurozone are all subject to the single monetary policy formulated by the ECB, which gives little regard to country-specific shocks (unless the shocks affect also the rest of the Eurozone or a sufficiently large part thereof). Therefore, individuals and regions which are vulnerable to idiosyncratic shocks, and which currently benefit from national fiscal transfers alleviating their hardship, may oppose EU accession on the grounds that it is a precondition of their country's eventual membership in the EMU.

In summary, accession to the EU is likely to have important and uneven implications for different socio-economic groups and regions. As the new member and candidate countries generally have highly skilled labor, as do the old member countries, standard economic theory offers little insight as to whether EU membership will translate into gains for high or low skilled labor in the new member countries. More broadly, we can predict that labor in general will gain while the holders of capital will lose out. Membership in the EU is also likely to adversely affect those sectors of the economy that continued to enjoy protection from formal and informal barriers to trade, most notably agriculture. Finally, regions and individuals vulnerable to idiosyncratic shocks are also likely to be made worse off by their country's accession to the EU, and especially by membership in the Eurozone.

3.2 Benefits from redistribution

The new members will also be included in the EU-wide system of redistribution including the Structural and Cohesion funds and the Common Agricultural Policy (CAP). The EU regional aid and the CAP are by far the largest two spending categories in the EU budget, with spending for 2005 (the first full post-enlargement year) budgeted at 32.4 billion and 49.1 billion euros, respectively (accounting for 31 and 47 percent of the overall EU budget).[12] Eligibility for regional

---

[10] One of the criteria is the obligation of membership in the Exchange Rate Mechanism for at least two years without realignment of the exchange rate, hence the minimum lag between EU and EMU membership is two years.
[11] See Vlachos (2004) and especially Jonung (2004) for further discussion.
[12] See European Commission (2004).

aid is directly related to the countries' and regions' level of economic development.[13] The bulk of Structural Funds goes to Objective 1 regions (approximately two thirds of funds), defined as those with per capita GDP below 75% of the union-wide average, and Objective 2 regions (accounting for about one-tenth of regional aid), which are those with above average unemployment and industrial employment and experiencing a decline in industrial employment. Transfers from the Structural Funds are disbursed at the regional level and are channeled mainly into projects that build up the productive capacity of regions, such as infrastructure improvements and small and medium enterprise development. Given the eligibility criteria, most of the new members' regions easily qualify for funding under Objective 1 or 2 or both. Eligibility for transfers from the Cohesion Fund is also determined according to per capita income: countries that are below 90% of the EU average GDP qualify. These transfers are allocated at the national level in contrast to the Structural Funds, and are mainly designated for large public investment projects. Again, all new member states meet the eligibility criterion in the enlarged EU.[14]

The ability of the new members to fully benefit from EU transfers however, will be limited, at least initially, due to the recently agreed reforms and transitional arrangements. In particular, the European Council in Berlin decided that the previously-agreed EU budget for 2000-06 would not be extended to finance this enlargement and therefore only modest transfers can be made to the acceding countries up until 2006. Thus, the new members receipts from the EU budget will amount on average to 1% of their GDP in 2004, rising to 1.5% by 2006 (11 and 16 billion euro, respectively, according to Barysch, 2003).[15] Moreover, EU transfers might, at least partially, displace any assistance that the depressed regions are receiving from their national governments at present (Vlachos, 2003, makes this argument with respect to Swedish regions' potential benefits and costs from their country's EU entry).

---

[13] Section 3.2 of Boldrin and Canova (2001) gives a detailed description of the various instruments of EU regional policy. Unless stated otherwise, the following discussion draws on their analysis.

[14] According to the Eurostat (2005) report citing statistics for 2002, only three NUTS 2 regions in the new member countries have per-capita GDP (in purchasing-power terms) above 90% of the EU25 average: one each in the Czech Republic, Hungary and Slovakia. Furthermore, Slovenia attains 75.3%, Cyprus 82% and Malta 74.2% of the EU25 average (these three countries each make up a NUTS 2 region on their own); no other new-member-country regions are between the 75 and 90% of the EU25 average GDP.

[15] These figures combine receipts from Structural and Cohesion Funds with the CAP.

A particularly controversial issue in regards the costs and benefits of enlargement is the application of the Common Agricultural Policy to the new members. The European Commission decided in January 2002 that the 10 acceding countries would receive initially only one-quarter of the subsidies paid to the old member states. This effectively implies that while agricultural markets in the new members are opened to competition from the current EU members, farmers in the new member countries do not enjoy the same level of subsidies as their competitors (their agricultural markets, nevertheless, are protected from imports from third countries).

In summary, the new members can expect to be net recipients of transfers from the EU budget. Since a large part of EU funds is disbursed directly to regions or even individual recipients (as is the case with the CAP), underdeveloped, poor, over-industrialized and/or agricultural regions (and individuals living in such regions) should benefit from redistribution more than others. The remainder of the paper studies how these potential gains translate into both voting intentions and behavior in the candidate countries' referenda on EU membership.

4. Data

The empirical analysis utilizes two previously untapped data sources: actual referenda results at the regional level, and survey data on intended voting in a future referendum on EU membership. The regional analysis is performed for seven countries: Czech Republic, Estonia, Latvia, Lithuania, Hungary, Slovakia and Poland (for the two remaining countries, Malta and Slovenia, either the regional referenda results or the corresponding socio-economic indicators were not available). The analysis with the individual data is based on the March/April 2002 Candidate Countries Eurobarometer (CCEB) opinion poll commissioned by the European Commission and carried out by Gallup Europe in all 13 candidate countries (i.e., also including Bulgaria, Romania and Turkey, in addition to the ten new members). The CCEB survey includes the responses of 14,163 individuals and contains extensive information on their socio-economic characteristics, in addition to their intended vote in the referendum on EU membership. The data set contains approximately 1,000 respondents per country, except for Cyprus and Malta with 500 respondents each and

Poland and Turkey with 2,000 each. The surveys were carried out by means of face-to-face interviews and are representative at the national level.[16]

Table 1 reports the support for EU membership as measured by the CCEB survey. While supporters of accession are the largest group in every country, several of the new member countries – the Baltics, Czech Republic, Malta, Poland and Slovenia – appear rather unenthusiastic about EU membership, with those in favor of membership accounting for 50% or less of all respondents. Ironically, the countries that were not invited to participate in the next enlargement – Bulgaria, Romania and Turkey – show particularly high support for EU membership. Clearly, the low share of supporters in some countries does not necessarily indicate high opposition to membership but rather reflects the fact that by early 2002, a non-negligible part of respondents remained undecided (12% on average). Nonetheless, the outcomes of the ensuing referenda reveal a similar pattern of reserved enthusiasm as Table 2 demonstrates (for Cyprus, where no referendum on accession was held, the table reports the result of the latest available opinion poll). The referenda results show that in all countries except Malta, a resounding majority of voters cast a vote in favor of their country's membership in the EU. However, again with the exception of Malta, high support for membership comes on the background of low participation rates. In fact, only in Lithuania and Slovenia did more than half of eligible voters endorse their country's EU membership. Low participation need not indicate indifference about the referendum's outcome. As all candidate countries, except the Czech Republic, had limits requiring a certain minimum participation (usually 50%)[17] for the referendum to be valid, not voting was just as effective (if not better) a strategy for an opponent of EU membership as voting against, especially when opinion polls conducted shortly before the vote predicted low turnouts. For example, had enough opponents of EU membership not voted, the turnout rates in Poland and Slovakia would have fallen below the 50% threshold. Thus, a voter who was opposed to accession was more likely to thwart the referendum by not participating than by voting against it.[18]

---

[16] Between one and two CCEB surveys were carried out per year since the Eurobarometer survey was extended to the candidate countries in 2001 but the primary data of these surveys so far have not been released publicly.

[17] In Hungary, while the turnout fell short of the 50% required threshold, the result was nonetheless valid in line with Hungarian law as more than one-quarter of the electorate voted Yes.

[18] It is not clear what would have happened if any country had failed to receive the popular endorsement for accession. Possible outcomes include submitting the decision to the parliament, repeating the referendum or staying out.

<Table 1 about here.>

To ascertain how participation in the referenda on EU membership compares with participation in regular elections, the last column of Table 2 reports the turnout rates recorded in the most recent parliamentary election in each country. In three cases (Hungary, Slovakia and Slovenia) turnout was lower in the referendum than in the previous election by ten percentage points or more, while the opposite was the case only for Poland. The remaining six countries are more or less equally split between those that had somewhat higher turnout rates in the referendum (Lithuania and Estonia) and those that experienced a small decline in turnout compared to the most recent election (Malta and the Czech Republic), with Latvia reporting almost no change. While strategic considerations may have contributed to low participation in some countries, this phenomenon is certainly not unambiguously evident in the data.

<Table 2 about here.>

Table 3 presents summary statistics for the dependent variables in the regional analysis – the share of those who voted in favor of their country's membership in the EU, in addition to the turnout rate. The analysis is carried out at the level of districts (the so-called *okresy* in the Czech Republic and Slovakia, *maakond* in Estonia, *rajons* in Latvia and Lithuania, *megye* in Hungary and *powiat* in Poland), with 77 observations for the Czech Republic, 16 in Estonia, 33 in Latvia, 60 in Lithuania, 20 in Hungary, 79 in Slovakia and 373 in Poland. As the mean vote shares are computed as average values across regions, they differ somewhat from the national figures reported in Table 1.

There is notably less regional variation in the Yes vote in the Czech Republic, Estonia, Slovakia, Lithuania and Hungary than in Poland and Latvia. In the case of Poland, this is due to relatively low support for EU membership in underdeveloped Eastern Poland, alongside the Ukrainian and Belorussian borders. In fact, all ten *powiats* with a majority vote against EU membership are located in Eastern Poland.[19] Similarly in Latvia, out of the five *rajons* which reported an overall majority vote

---

[19] These *powiats* were Janowski, Wysokomazowiecki, Skierniewicki, Siedlecki, Lomzynski, Losicki, Radzynski, Zamojski, Wegrowski and Lubelski.

against membership, four are bordering either Russia or Belarus.[20] None of the regions in the Czech Republic, Estonia, Lithuania, Slovakia or Hungary reported a majority vote against accession. In all seven countries, turnout displays considerable variation across regions; in the Czech Republic and Hungary, turnout varies much more than the Yes vote (the corresponding coefficients of variation are 6.9% for turnout vs 3.1% for the Yes vote in the Czech Republic and 11.1% and 2.3%, respectively, in Hungary).

Table 4 reports the summary statistics for the socio-economic indicators used to explain voting and turnout at the regional level.[21] All seven countries report considerable regional variation in unemployment and wages. While unemployment is moderate in the Czech Republic and Hungary, it reaches double digits in Latvia, Estonia, Slovakia and Poland. Finally, Poland stands out among the new members as having a large share of employment in the agricultural sector.[22]

<Table 3 about here.>
<Table 4 about here.>

5. Regional determinants of support for EU membership

As Tables 1, 2 and 3 illustrate, support for EU membership, as revealed in the opinion polls and the actual referendum results, varies considerably across and also within countries. The variation in turnout is even greater. The first step in the analysis therefore is to study the determinants of support for EU membership and turnout as reflected in the regional results of the EU accession referenda. Both support for membership and turnout are analyzed separately, as it is possible that those who opposed EU membership may have chosen not to vote, hoping that their abstention would be more effective in keeping the turnout below the legally mandated minimum threshold, thus rendering the result invalid. As the primary interest of this paper is to determine whether patterns of support can be generalized across the seven candidate countries and because each referendum was held with essentially the same underlying

---

[20] The five *rajons* were Daugavpils city, Daugavpils, Rezekne, Kraslavas and Ludzas.
[21] Descriptive statistics for the individual-level analysis are omitted to save space. They are available from the authors upon request.
[22] Table 4 reports simple, unweighted means of the various indicators. Nation-wide, nearly 20% of Polish employment is in agriculture.

question, the regional data is pooled across all countries. That is not to say that country-specific aspects of support for EU membership are unimportant or uninteresting. On the contrary, the fact that country dummies are always significant implies that there are in fact important differences in voting behavior and turnout across countries. However, reporting and discussing these differences properly would greatly extend the scope of this paper, and, given our objective – identifying patterns of support for European integration shared by all new member and candidate countries – would ultimately entail little added value. We therefore limit ourselves – in this section as well as in the following one – to pointing out the differences in support and turnout across countries implied by the significant coefficients on the country dummies, without going too far in attempting to explore the sources of these differences.[23]

The choice of explanatory variables for the pooled regressions is dictated by the need to find the 'smallest common denominator' in terms of availability and comparability of data across countries. Therefore, both support for membership and turnout are regressed on regional unemployment rates, average wages and employment in the main branches of the economy: agriculture, industry (which also includes construction), and services (as the omitted category). All regressions also contain country dummies.

The results obtained with support for EU membership are reported in Table 5, while those with participation are in Table 6. Four regression equations are reported in each table. First, support and participation are regressed on regional unemployment and average wage alone, then the shares of employment in agriculture and industry are added and finally, a dummy that distinguishes districts surrounding major urban centers in the Czech Republic, Hungary, Slovakia and Lithuania is added to the previous two regression specifications.[24] This last dummy is included to distinguish suburban regions from other rural areas that may have similar economic conditions but are far away from major cities – residents of suburban regions often work in the nearby city and therefore their political preferences may be closer to those of urban

---

[23] Results of the country-by-country analysis of the regional voting patterns, including results obtained with additional explanatory variables are available from the authors upon request. Markowski and Tucker (2003) and Hazans (2003) present more detailed case studies of Poland and the Baltic countries, respectively.

[24] These urban centres are the following (with the corresponding suburban regions in parentheses): Prague (Prague East and West), Plzen (Plzen South and North and Rokycany), Brno (Brno-vicinity), Budapest (Pest), Bratislava (Malacky, Pezinok and Senec), Kosice (Kosice-vicinity), Alytus (Alytus-region), Kaunas (Kaunas-region), Klaipeida (Klaipeida-region) and Vilnius (Vilnius-region).

dwellers rather than to those of rural residents. The results for support and participation are quite dissimilar, suggesting that different considerations were driving voting behavior and participation in the referenda. The unemployment rate is positively related to support for EU membership (although it is only significant after the structure of employment is controlled for). In contrast, high unemployment rates translate into lower participation in the referenda. The opposite holds for the average wage (although the estimated coefficients are at best marginally significant): it appears with a negative sign in the regressions for support and with a positive sign in those for participation. As discussed above, it is not clear whether lower turnout in high-unemployment and low wage regions (with the qualification that the results for the average wage are not highly significant) indicates indifference or opposition towards EU membership. Nevertheless, these results show that while depressed regions tend to have a significantly lower turnout rate, the voters who do cast their votes in these regions show greater support for EU membership, possibly in anticipation of membership improving their regions' economic malaise.

<Table 5 about here.>
<Table 6 about here.>

The second columns show that when employment in the main sectors of the economy is added (except for Latvia and Lithuania for which comparable employment data are not available), the share of employment in agriculture is negatively correlated with support for EU membership and (along with the share of employment in industry) also with turnout. Thus, it appears that workers in these sectors fear they will lose out, or at least, do not expect to benefit as much from accession compared to the service sector (the omitted category). In particular, the negative impact of employment in agriculture on support for accession and turnout may also reflect fears concerning the opening up of the market for agricultural goods and disappointment with the low level of subsides from the CAP that the farmers in the new member countries will receive. Similarly, the negative coefficient obtained for industrial employment may be motivated by fears that membership in the EU will accelerate the downsizing of inefficient firms – both because of the increased competitive pressure and due to the application of EU restrictions on subsidies to ailing firms.

Suburban districts display higher support for membership and higher participation than regions with comparable economic conditions that are further away from major cities (however, the coefficient is only significant when the regressions include the employment variables). This suggests that economic conditions in the adjacent urban region (which tend to be more favorable than conditions in rural areas) have an important impact on suburban voters' political preferences.

Finally, the coefficients on the country dummies are all strongly significant, both for support and participation, indicating that there are important differences in support for EU membership across countries beyond those can be attributed to different objective economic conditions (at least as measured by the very basic indicators used in this analysis). Hungary, Slovakia and Lithuania display higher support for membership than the Czech Republic (the omitting category), while Poland, Estonia and Latvia display lower support.[25] In regards turnout, the Estonians, Latvians and Lithuanians were more likely to participate in the referendum than the Czechs (the omitted category), while the Polish, Hungarian and Slovaks were less likely to vote. Comparing these coefficient estimates with the figures on votes supporting accession and turnout reported in Table 2, we see that the ordering of countries according to both measures remains virtually unchanged even after controlling for a number of regional determinants of voting behavior. This indicates that the country-specific components of support for EU membership and participation in the EU accession referenda are largely uncorrelated with the explanatory variables included in our regressions. Hence, the factors behind these inter-country differences do not seem to be related to the local economic conditions (at least they are not related to such admittedly crude economic measures as unemployment, average wages, and sectoral structure of employment).[26]

---

[25] It is noteworthy, however, that Poland appears relatively unenthusiastic about EU membership only when the regressions fail to control for the shares of employment in agriculture and industry and construction. This seems to suggest that the low support for accession in Poland was particularly due to the negative attitudes of farmers and agricultural workers. Once agricultural employment is included in the regression, it appears with a strongly significant negative coefficient, while the Polish dummy appears with a significantly positive and sizeable coefficient.
[26] These differences may reflect factors such as social, cultural, historical and political factors in addition to economic considerations. A deeper and more profound analysis, which would go beyond the scope of the present paper, would be required to navigate within such a diverse spectrum of potential explanations.

6. Individual determinants of support for EU membership

The previous section found that support for membership was higher but turnout was lower in depressed regions. It also observed that both support for accession and turnout were lower in regions with a large share of employment in agriculture and industry. These results were obtained at an aggregate level – by analyzing regional variation in support for membership and participation. While these results yield valuable insights for our understanding of pro-EU sentiments in the candidate countries, as they were obtained at the regional level, their extension to the individual-voter level is not straightforward. Therefore, this section extends this analysis by using data from the March/April 2002 CCEB survey.

6.1 Determinants of voting intentions

The dependent variable is based on responses to the following question: "And if there were to be a referendum tomorrow on the question of (our country)'s membership, would you personally vote for or against it?" The possible answers included: "for", "against", and "I would not go to vote". As in the preceding section, both the support for EU membership and participation in the referendum are considered. As "not going to vote" was presented as one of the alternatives in parallel with voting for or against accession, the respondents' choices are analyzed jointly by means of a multinomial logit regression (see Alvarez and Nagler, 1998, for a discussion of the applicability of different statistical methods to decisions situations with multiple choices). This method requires that one of the choices is designated as the base category, therefore, to make the interpretation of the coefficient estimates straightforward, "voting against" is designated as the base category.[27]

A number of socio-economic factors are included among the explanatory variables: gender, marital status, age (including a quadratic term), number of children in the household, number of household members, dummies for education, occupation

---

[27] A Heckman Probit Selection model was also estimated due to a possible selection bias, whereby the voters' decision could unfold in two steps: first, they must decide whether to vote or not, and, second, contingent on the outcome of the first-stage decision being affirmative, they must then decide whether to vote Yes or No. However, both theoretically and empirically the Heckman Probit model was an inappropriate choice. First, given that the question asked in the survey was posed within a single question with 3 choices 1) Vote Yes, 2) Vote No, 3) Do Not Vote, the respondent had to make the decision simultaneously, not sequentially as assumed by a Heckman Probit. Second, due to the high number of parameters, the model would only converge when the majority of the explanatory variables were excluded.

and place of residence (village, small town or city), respondents' history of unemployment (number of unemployment spells over the past five years) and household income or standard of living. Concerning the latter, regressions estimated using self-assessed well-being (rich, comfortable, average, getting along or poor, with rich/comfortable being the reference category) are reported. The results obtained with nationally-based income quartiles and an indicator stating whether the respondent considers their household income higher than necessary, sufficient or insufficient to meet their needs are qualitatively very similar and therefore are not reported (they can be obtained from the authors upon request). Finally, country dummies are also included to take account of country specific effects.[28]

The results are presented in Table 7. The first column presents the coefficient estimates for the probability of choosing *"vote in favor"* compared to *"vote against"*. The second column, similarly, reports the coefficient estimates characterizing the probability of choosing *"will not vote"* compared to *"vote against"*. In addition, as the coefficients in MNL models are difficult to interpret, marginal effects are also reported beside the coefficient estimates. The marginal effects quantify the impact of each variable on the probability of the respondents' choice being either *"voting in favor"* or *"not voting"* rather than *"voting against"* (note that the marginal effect need not necessarily be of the same sign as the coefficient in question, see Train, 2003, pp. 61-63).

<Table 7 about here.>

In order to interpret how the various factors affect respondents' choices over the three alternative courses of action (voting in favor, voting against or not participating), one has to consider both sets of results jointly. Accordingly, women are less likely than men to participate in the referendum, whereas the opposite holds for married respondents. However, neither gender nor marital status is correlated with supporting membership among those who intend to vote. Older respondents are less likely to choose either voting in favor or abstaining, suggesting that age is correlated with the probability of voting against EU membership (the relationship is U-shaped,

---

[28] As argued in the preceding section, we are predominantly interested in patterns of support for EU membership that can be generalized across all new member and candidate countries rather than in country-specific considerations. Therefore, we only report results obtained with data pooling all countries together.

so that support and non-participation start increasing again once the respondent reaches 50 years of age). Higher education and being a student both increase the likelihood of participating and voting in favor of EU membership. Having a white-collar occupation, a higher standard of living (or higher income), and living in a town or city are all associated with higher support for accession but do not affect the choice between voting against or not participating. Current unemployment and having experienced two or more unemployment spells in the past have an opposite effect on participation, suggesting that unemployed respondents are more likely to participate, except for those who have a history of multiple past unemployment spells. Neither being currently unemployed nor having had unemployment spells in the past, however, affects the respondents' support for the EU (unemployment may lower support for accession indirectly because it lowers the respondents' well-being but does not appear to have an effect going beyond that). Farmers, finally, are less likely to cast a vote in favor of EU membership and, even more so, less likely to abstain, indicating that farmers are quite strongly opposed to entering the EU.

It is instructive to compare the magnitudes of the effects of the different variables. By far the most important determinants of support are those that our analysis largely fails to explain: the country specific effects captured by the country dummies (note however, that although the country dummies also appear with strongly significant coefficients in the equation for participation, the corresponding marginal effects are substantially lower). For example, all else equal, the Poles, Czechs, Slovenes, Estonians, Latvians and Maltese are 40-50% less likely to favor EU accession, while the Romanians are 13% more enthusiastic than Bulgarians (the omitted category) about their EU entry. Nonetheless, the individual socio-economic characteristics have an important impact on voting behavior as well (when comparing the relative importance of individual and country-specific factors, note that while we control for a large number of individual characteristics, the country dummies are catch-all variables capturing the cumulative effect of a host of different factors including, besides economic considerations, political, cultural and historical influences). Income and material well-being appear to exert a particularly strong effect on support for EU membership: respondents who report average well-being (as opposed to comfortable, very comfortable or rich) are 8% less likely to support accession while those who consider themselves getting along or poor are 14% and 23%, respectively, less likely to vote in favor of the EU entry. Education and

occupation have more modest impact: respondents with secondary education are 5% more likely to support the EU, those with a university education or are still in school are 8% more likely to be in favor, while white-collar occupation raises the probability of voting yes by 4%. The effect of education on the probability of not voting is approximately half as strong: 3-4%. Farmers are approximately 3% less likely to vote in favor of EU membership and also 3% more likely not to vote at all. Finally, age has a u-shaped effect both on the probability of voting in favor of EU membership and on the probability of not voting: it is negative for the young to intermediate age range, levels off around the age of 50 (58 for not voting) and becomes positive for higher age.

The theoretical arguments discussed in Section 3 and the empirical evidence presented by O'Rourke and Sinnott (2001), O'Rourke (2003) and Mayda and Rodrik (2001), suggests that the relationship between education and skills should depend on the relative scarcity of human capital in the country in question: skilled and educated workers should support integration in human-capital abundant countries, and oppose it in human-capital poor countries. While we have argued that this dichotomy is less likely to be present in our data set as it includes largely similar countries (medium-income economies with relatively highly skilled and educated work forces), the simplest possible test can be performed by excluding those countries that deviate the most from the rest in terms of their human-capital endowments. When we rerun the regressions while excluding all observations for Turkey, being the poorest country in our sample, or those for Turkey, Bulgaria and Romania as the three poorest countries,[29] the coefficient estimates for education and occupation (in particular for white-collar workers and farmers) increase slightly in both size and significance for those who intend to vote in favor and remain almost unchanged for those who do not intend to vote. Thus, while the relevant coefficient estimates change in the expected direction, the impact is by no means dramatic, thus confirming our prior reasoning.

---

[29] These results are available from the authors upon request. Turkey clearly is not only the economically poorest country but also human-capital poorest country in our data set: 63% of respondents have primary (or lower) education (compared with the sample average of 26.3%) and only 7.6% have university education (the sample average is 20.7%). Romania and Bulgaria, on the other hand, are both very close to the sample average on both measures. The other countries that stand out are Malta with respect to university education (7.9%, the only other country with university-educated respondents accounting for less than 10%), and Malta, Hungary and Cyprus with respect to primary education (37.9%, 39.2% and 42.3%, with all the remaining countries having less than 30% of respondents with primary or lower education). Dropping Turkey, Malta, Hungary and Cyprus, however, weakens the results for the impact of education on support for the EU, which is contrary to the theoretical prediction (results available upon request).

Even after controlling for individual characteristics, the country dummies remain strongly significant, indicating that there are important differences in attitudes towards the EU at the aggregate level. Again, as was the case with the results of our regional analysis, the ordering of countries implied by the coefficients on country dummies, especially in the Yes-vote regression, is similar to the patterns of support revealed by the actual referenda. Again, this can be interpreted as an indication that although individual determinants of support and participation clearly are important, there remains a considerable country-specific component of support for EU membership that cannot be explained by differences in individual endowments and socio-economic characteristics across countries. In particular, most countries, with the exception of Romania and Hungary, are less supportive of the accession than Bulgaria (which is the omitted country), with Malta, Estonia, Latvia and Slovenia appearing especially skeptical about accession. Interestingly, Turkey, which appeared strongly pro-EU (along with Bulgaria, Hungary and Romania) when reviewing aggregate numbers, turns out less enthusiastic about EU membership after individual characteristics are controlled for. It is interesting to note that Bulgaria, Hungary, Romania and Slovakia, which show relatively high rates of support for EU membership, have also higher rates of intended non-participation than the other countries. This indicates that the high aggregate levels of support for EU membership in these countries may in fact disguise the fact the opponents of accession tend to choose non-participation rather than cast a negative vote.

6.2 Attitudes towards the EU versus voting intentions

The analysis so far could only investigate support for EU membership among those respondents who indicated that they would participate in the referendum. This is dictated by the data, as the respondents who did not intend to vote (or were undecided) were not asked which outcome they, nevertheless, prefer. It is possible, however, to obtain an insight into the preferences of abstainers by using a question that asks respondents whether they think their country will benefit from EU membership ("*Taking everything into consideration, would you say that (our country) could get advantages or not from being a member of the European Union?*"). Cross-tabulating responses to this question with those on intended voting indicates that voting intentions are indeed closely correlated with expectations on gains from membership:

only approximately 5% of those who intend to vote in favor of accession think that their country would not gain from it; among those opposed to EU membership, 15% expect their country to gain nonetheless.

Respondents therefore can be divided into four groups: (1) those who believe their country will not benefit from membership and do not intend to participate, (2) those who believe their country will not benefit from membership but intend to participate, (3) those who believe their country will benefit from membership but do not intend to participate, and (4) those who believe their country will benefit from membership and intend to participate. Again, a multinomial logit model is employed to analyze respondents' decisions over multiple choices. The EU pessimistic respondents who intend to vote, i.e. the second group, (this being the second largest category of the four) is designated as the base category. Regression results with income measured again by self-reported well-being are reported in Table 8.[30]

The results for the EU optimists who intend to vote are similar to those obtained above for the Yes vote – not surprisingly, as the two regression equations are estimated over very similar supports. As before one should consider results across all three categories jointly to make proper inferences about attitudes towards the EU. Women are less likely to participate, however, there is little difference between those who are optimistic and those who are pessimistic about EU membership. Married respondents are less likely to be non-voting pessimists and therefore, more likely to belong in any of the three remaining categories. Both of these results further refine the findings reported previously. The probability of being an optimist (voting or not) falls with age so that older people tend to be less enthusiastic about accession, but the effect again appears U-shaped, at least for those who intend to vote, and becomes positive after reaching approximately the age of 62. Students, those with university education and white-collar professionals are more likely to be optimists and cast their vote and less likely to be non-voting pessimists (i.e., education and skill are also positively correlated with overall participation). Again, farmers appear strongly skeptical about entry into the EU. The pattern for subjective well-being is similar across all three categories: poorer respondents are less likely to belong to any category and thus are more likely to be pessimistic about accession and also participate in the referendum; this effect is particularly strong for the least affluent group. Finally, while

---

[30] The results with the other two measures of income are qualitatively very similar and therefore are not reported here but can be obtained from the authors upon request.

current unemployment does not significantly affect any category, those who had been unemployed at least twice in the past are more likely to be optimistic about accession, but abstain from voting. Thus, while unemployment experience does not make people more pessimistic about EU membership, it does discourage them from voting in the referendum – a finding that is similar to the one obtained for unemployment in the regional analysis. Finally, the relative importance of the various determinants of attitudes is similar as with voting behavior discussed in the preceding sub-section: broad country-specific factors have the strongest impact on the probability of espousing an optimistic attitude towards the EU and intending to vote, followed by income and material well-being and education. The marginal effects estimated for the remaining categories are much lower in magnitude.

<Table 8 about here.>

7. Conclusions

EU membership is widely expected to bring large gains to the ten countries that entered in May 2004. Yet, in recent opinion polls as well as in the referenda on accession that took place in the course of 2003, support for EU entry was far from overwhelming. In a few cases (for example Malta, the Czech Republic and Estonia), it even appeared conceivable beforehand that the referendum would not pass. Although all the referenda eventually resulted in an endorsement for accession, these high rates of support often disguised very low rates of voter turnout. In some countries (e.g., Poland and Slovakia), the turnouts barely exceeded the legally mandated 50% threshold that was required to make the vote binding.

This paper sheds some light on these developments by analyzing the regional and individual determinants of support for accession and voters' participation in the referenda. We argue that accession will affect the citizens of the new member countries in two ways: through efficiency gains and new economic opportunities arising from accession to the European Single Market, and by being included in the EU-wide system of redistribution via Structural and Cohesion funds and the Common Agricultural Policy. However, each effect will have different implications for the various socio-economic groups, with some gaining and others undoubtedly losing. By relating voting behavior in the referenda or voting intentions as expressed in opinion

24

polls to regional and individual socio-economic characteristics, it is possible to identify the winners and losers of this EU enlargement.

The empirical results suggest that those with favorable and relatively flexible human capital tend to support EU membership. In particular, those with high education (or still in school), white-collar occupations, high income, young age and living in urban areas are more likely to participate in the accession referenda and vote in favor of EU membership. Similarly, regions with favorable economic conditions (low unemployment and high wages) display greater turnout (albeit not greater support). In contrast, and surprisingly, those who should in principle benefit from redistribution in the EU – the elderly, blue-collar workers, less educated, those with repeated history of unemployment, those living in rural areas and also those living in underdeveloped or agricultural regions – tend to be against accession and/or do not vote. Hence, it appears that the nationals of the new member states tend to put a greater weight on the gains from improved efficiency and new opportunities, while they discount the potential benefits from receiving subsidies from the richer EU member states. The latter conclusion appears surprising at first sight, however it seems warranted given that the transfers which the new members will receive have been revised and in effect scaled down considerably compared to earlier expectations and also relative to the transfers received by other less developed entrants in the wake of previous enlargements.

Another plausible explanation is that voters perceive accession to the EU as a natural continuation, and indeed ultimate outcome, of the post-communist transition from central planning to a market economy, and therefore their support for EU membership reflects whether they gained or lost from market-oriented reforms (and whether they expect to gain from further liberalization and intensification of competition). Indeed, the supporters of EU membership tend to have similar socio-economic profiles as the voters of liberal, pro-reform parties (see Fidrmuc, 2000a,b; Jackson, Klich and Poznańska, 2001; Doyle and Fidrmuc, 2003; and Doyle, 2004.[31] Furthermore, membership in the EU, and eventually in the EMU, will impose important constraints on national fiscal policy and thus the ability of governments to compensate those made worse off by accession as well as the on-going reform process

---

[31] A study by Tucker, Pacek and Berinsky (2002), using the 1996 Eurobarometer survey, also found that regardless of demographic characteristics, the "winners" from transition are more likely to support accession to the EU than the "losers".

(Vlachos, 2003, makes a similar point about voting in the Swedish referendum preceding that country's EU entry in 1995).

Finally, and importantly, these findings show that voters in the new states supported accession holding greater efficiency and economic integration rather than fiscal transfers as their primary motivation. There is little political will among the EU-15 members to finance this enlargement by extending the transfers and subsidies to the ten new member countries without a substantial reform of the redistribution system. The voters in the new members appear to be aware of this but they approved the accession nonetheless. Thus, while the scaling down of the scope for transfers and subsidies (relative to initial expectations) probably helped drive down the support for EU membership, the other benefits (efficiency improvements but also increased political and economic stability) made the prospect of EU membership sufficiently attractive to sway a critical mass of voters in favor of accession.

Slovakia	52.2	93	7	48.5	May 17, 2003	70.0 (2002)
Poland	58.9	77	23	45.4	June 7-8, 2003	46.3 (2001)
Czech Republic	55.2	77	23	42.5	June 13-14, 2003	58.0 (2002)
Estonia	63.0	67	33	42.1	Sept. 14, 2003	58.2 (2003)
Latvia	72.5	67	32	48.6	Sept. 20, 2003	71.5 (2002)

Source: Gallup Europe, Enlargement Poll Monitor (http://www.gallup-europe.be/epm/), and Electionworld.org.
Notes: Candidate countries are ordered chronologically, according to the referenda dates. Only countries that will be part of the next enlargement are included.
[a] Percentage of eligible voters who supported accession.
[b] Cyprus approved EU membership without holding a referendum; the results of the latest available opinion poll are therefore reported.
[c] Participation rate in the most recent parliamentary election (the year to which the figure refers is in parentheses).

Table 3
Regional Results of EU Referenda

Country	Turnout [%]		Yes Vote [%]	
	Mean	St.Dev.	Mean	St.Dev.
Czech Republic	55.36	3.82	76.33	2.33
Estonia	62.46	3.38	65.33	4.03
Hungary	44.32	4.96	84.25	1.93
Latvia	70.91	5.51	69.36	13.31
Lithuania	63.25	5.70	90.40	3.52
Poland	56.11	5.82	74.35	10.33
Slovakia	51.27	5.59	92.82	2.35

Notes: Means are computed as averages across regions and as such are different from the nationwide results reported in Table 1.

Table 4
 Descriptive Statistics of Regional Indicators

Country	Unemployment Rate [%]	Average Wage [local currency]	Agriculture [%]	Industry and Construction [%]
Czech Republic	9.94 [c]	13,940.82 [c]	6.90 [c]	48.74 [c]
	(4.15)	(1363.39)	(4.34)	(7.96)
Estonia	10.88 [d]	5,073.94 [d]	12.63 [d]	31.69 [d]
	(3.88)	(999.24)	(6.89)	(5.34)
Latvia	11.65 [e]	119.09 [b]	~	~
	(6.52)	(24.08)

	(4.93)	(156.64)		
Hungary	6.07 [c]	91,059.95 [c]	5.85 [c]	39.99 [c]
	(2.07)	(13252.59)	(2.38)	(7.45)
Poland	17.77 [b]	1,636.86 [a]	41.35 [b]	26.20 [b]
	(6.55)	(220.93)	(24.74)	(12.91)
Slovakia	15.09 [e]	12697.23 [e]	6.86 [e]	40.96 [e]
	(6.88)	(2600.43)	(3.43)	(8.53)

Sources: Regional data was obtained from the central statistical offices of the individual countries.
Notes: Agriculture, industry and construction are expressed as shares in total employment. Means are computed as averages across regions (standard deviation in parenthesis) and as such are different from the nationwide values. Data pertain to: [a] 1999; [b] 2000, [c] 2001; [d] 2002; [e] first half of 2003.

Notes: Coefficient estimates and marginal effects are reported with heteroskedasticity-robust standard errors in parentheses. The dependent variable corresponds to the following question: "*And if there were to be a referendum tomorrow on the question of (country)'s membership, would you personally vote for or against it?*" Possible answers are 'for', 'against', and 'will not vote'. Both equations are estimated jointly by multinomial logit with 'will vote against EU membership' being the base category. The omitted categories are: male, not married or not cohabiting, primary education, manual worker, no past unemployment experience, rich/very comfortable/comfortable well-being, village/rural area, and Bulgaria. Significance levels: *** 1%, ** 5% and * 10%.

Notes: Coefficient estimates and marginal effects are reported with heteroskedasticity-robust standard errors in parentheses. All three equations are estimated jointly by multinomial logit with 'EU pessimist – will participate' being the base category. The dependent variable combines answers to the question "*Taking everything into consideration, would you say that (country) could get advantages or not from being a member of the European Union?*" with an indication on intended participation in the referendum on EU membership. The omitted categories are: male, not married or cohabiting, primary education, manual worker, no past unemployment experience, rich/comfortable well-being, village/rural area, and Bulgaria. Significance levels: *** 1%, ** 5% and * 10%.
